

Peptide activating macrophages

Immunomodulation provides new therapeutic opportunities through the re-engagement of the immune system against body dysfunction (pathogen infection, oncogenesis, etc.). In particular, macrophage polarization enhances phagocytic capacity as body's first line of defence.

DESCRIPTION*

- Naturally occurring recombinant peptide:
 - Able to activate macrophage's cytotoxic functions against pathogens recognized by type C lectin receptors (bacteria, fungi, yeast, parasites) and tumor cells
 - Enabling the production of pro-inflammatory cytokines
 - Displaying no direct microbicide activity
 - Depicting no evident cytotoxicity (on human erythrocytes and monocytes)
- *In vitro* and *in vivo* efficacy data on murine model of *Candida albicans*
- *In vitro* efficacy data on lymphoma model

Proposed mechanism for macrophage polarization by the peptide.

COMPETITIVE ADVANTAGES

- Specific immunomodulation action limiting the rise of resistance
- Potential of synergetic action with existing drugs
- Short sequence peptide:
 - Simple to manufacture
 - Cheap

APPLICATIONS

- Anti-infectious agent: bacteria, fungi, yeast, parasites
- Anti-tumor agent
- Pro-inflammatory agent

INTELLECTUAL PROPERTY

- Patent pending

DEVELOPMENT STAGE

- Experimental proof of concept

LABORATORY

- BTBS, Pharma-Dev and DC2N laboratories
